

Building My Weather Station

Category: Environmental Monitoring | Status: Completed Prototype | 6 min read

A local weather station using Arduino, a DHT11 sensor, RTC module, and display to track temperature and humidity.

Materials

- Arduino UNO
- DHT11 temperature and humidity sensor
- RTC module
- LCD or OLED display
- Breadboard
- Jumper wires
- USB cable or battery source

What I learned

- Weather data is local and depends heavily on sensor placement.
- Time-stamping makes environmental data more useful.
- Simple data collection can lead naturally into data science questions.

Safety or accuracy note

Low-cost environmental sensors need calibration and should be treated as approximate indicators, not certified measurements.
